

Candidate Marks Report

Series : 6 2018

This candidate's script has been assessed using On-Screen Marking. The marks are therefore not shown on the script itself, but are summarised in the table below.

Centre No :	Assessment Code :	H567
Candidate No :	Component Code :	02
Candidate Name :		
Total Marks :		

In the table below 'Total Mark' records the mark scored by this candidate.
'Max Mark' records the Maximum Mark available for the question.

SECTION A – Core studies

Answer all the questions.

- 1 (a) From Baron-Cohen et al.'s study on autism in adults:

- (i) Explain why this study is considered a quasi-experiment.

The study is considered a quasi-experiment as the IV which was being tested uses a naturally occurring variable for example whether the participant had ^{ranging from Asperger's to autistic} [2] syndrome

- (ii) Outline the findings in relation to the Strange Stories task.

In the Strange Stories test found similar results to the main finding. Thus the high functioning autistic adults and those with Asperger's syndrome scores significantly lower than the control of female participants [2]

- (b) From Freud's study of Little Hans:

Explain why the study can be considered a longitudinal study.

Some of the accounts given went back to when Hans was around 3 years old up until around 6 years old. Instead of only meeting one time Freud met Hans on at least two occasions over time and is therefore a long duration study. [2]

- 2 (a) Describe how Gould's study 'A nation of morons' links to the key theme 'Measuring differences'.

Gould aimed to measure intelligence through psychometric testing of 1.25 million army recruits. In his study participants varied from educated white Americans to for example, African Americans, Polish participants. This links to the theme Measuring differences as a variety of ethnicities, ages, upbringing and educations were used and tested in a variety of ways. This links to the other part per.

[4]

- (b) From Hancock et al.'s study into the language of psychopaths:

- (i) Identify the sampling method used.

The sample used opportunity sampling as researchers simply interviewed participants from one facility willing to take part. [1]

- (ii) Explain why participants were interviewed at the beginning of the study.

They were interviewed to gather if they were psychopaths or non-psychopaths but also the types of murder or crime ie - manslaughter and then asked to re account their on series of events. [2]

- 3 Explain why Bandura et al.'s study on the transmission of aggression can be placed in the developmental area.

The developmental area argues both nature and nurture play a role in developmental behaviour. This fits in with Bandura's study as he found that boys were more likely to channel their aggression than girls following a scene - sex model. This shows how behavior behaviour can be nurtured as they observed and imitated but nature can also play a role as typically aggression is a male quality. [3]

- 4 From Blakemore and Cooper's study into the impact of early visual experience:

Briefly describe how the visual environment in which the kittens were reared was manipulated.

The visual environment of the kittens either each spent 5 hours a day in their visual environment which for one was a cylinder showing only vertical line with a see through floor and another was the same cylinder structure however, using horizontal lines. [2]

- 5 (a) From the study by Loftus and Palmer on eyewitness testimony:

Outline two ways in which the procedure was standardised.

- One way the procedure was standardised was by using the a ~~different~~ (abortion research method). This allowed for set instructions and procedure to be followed so every participant experienced the same experience. Another ~~method~~ was by controlling or attempting to control extraneous variables.

[4]

- (b) To what extent does Grant et al.'s contemporary study into context-dependent memory change our understanding of the key theme of 'Memory'? Support your answer with examples from both Loftus and Palmer's and Grant et al.'s studies.

Grant's study changes our understanding as rather than support previous research showing silent conditions mount better recall he demonstrated how noise of silence makes no difference to memory recall in a test only that the conditions study showed in were matching i.e. noisy (background music in a cafeteria) and noisy recall. Loftus and Palmer also changed our understanding of memory by showing how eye witness testimonies aren't as reliable as might have originally been thought as memory can respond to response bias or even be distorted as findings showed those who heard something opposed to hit for example remember breaking glass which was ^{never present} never present.

[5]

- 6 (a) From Moray's study into auditory attention:

Describe the research method used in Experiment 2:

It was an independent research method design as they used a laboratory experiment. Each participant listened to the shadowed message and their names were said in the unattended ear either at the start or in the middle of the message. If the participants forgot their names broke the blo.

[3]

- (b) From Simon and Chabris's study into visual attention:

Outline the 'gorilla condition'.

The 'gorilla condition' consisted of a woman dressed in a costume walking across the teams in the video either in opaque or transparent setting. Groups consisted of two teams of three either black or white coloured t-shirt teams running from a hard condition (Cuenda) or an easy condition (banan sasses). The gorilla was smaller than the other in the hard condition and did not interact with participants.

[3]

- 7 Outline one difference between Milgram's study of obedience and Bocchiaro et al.'s study into disobedience and whistleblowing.

One difference is that in Milgram sample 40 male participants were used from an average age range of 20-50 using a self selecting sample. Although Bocchiaro used the same sampling method his sample was very different as he used both genders of university students which would have been around the same age as Milgram's 20-50 age range.

SECTION B – Areas, perspectives and debates.

Answer all the questions..

- 8 (a) Describe the concept of freewill.

Freewill is the belief that the choices we make are down to our own inhibition and not as a result of e.g. environmental factors.

[2]

- (b) Explain how Lee et al.'s study on evaluations of lying and truth-telling may support the view that behaviour is determined.

Lee's study found although overall lying was rated as bad and truth as high there were differences in the Chinese and Canadian children. Chinese rated lying in a prosocial environment as good in some circumstances as their culture modesty is taught and begging for praise looked down upon. This shows how depending on culture, upbringing and environment behavior is influenced.

[3]

- (c) Suggest why research in the individual differences area is often considered socially sensitive. Support your answer with examples from relevant core studies.

It can be considered socially sensitive as it looks at such socially sensitive participant groups for example, in Baron and Cohen's study participants on the autistic spectrum are hard to gather and test in an environment that is ^{not} socially sensitive to research. Projects such as Little Holes included ~~participants~~ the participants name, age and location which is not socially sensitive given the nature of the study or in any circumstance as it breaks the child's right to privacy and confidentiality. Using a small child who is unable to consent themselves is also socially sensitive as his father being a Freud supporter may have forced his son in order to do research.

[5]

- (d) Describe **two** weaknesses of the individual differences area. Support your answer with examples from relevant core studies.

- The individual differences area is often seen as ^{reductionist} determinist. A range of factors can influence an individual from cognitive (mental processes) to biological (hormones). Behaviour cannot simply be down to individual differences as we are influenced by many factors. Another weakness is that it lacks in scientific status meaning behaviour for example, little plans aren't as controlled or standardised as for example species biology are study which could mean less replicability and therefore reliability [4]

- (e) Compare the individual differences area with the behaviourist perspective. Support your answer with examples from relevant core studies.

In individual differences one argues behaviour can be understood in terms of dispositional factors. This compares to the behaviourist perspective in which one argues we are products of our environment and acquire behaviour through learning. Hence it's study into the language of psychopaths show the individual differences in behaviour are down to ^{individual factors} and ^{is} simply who we are e.g. psychopaths - non-psychopaths. Whereas studies like Bandura support the behaviourist perspective as them demonstrate how this violent or aggressive behaviour can be understood through observational learning consisting of the observation and imitation of model i.e. adults. The behaviourist perspective generalise similar behaviour to everyone may be considered. Nettle et al. (14) suggest argues we all learn through certain [6]

- (f) Explain why Chaney et al.'s Funhaler study can be considered useful.

It's useful as it provides applications such as an increase in young asthmatics taking their medication at the right amount and online reducing admissions to hospitals or doctors with asthma related problems. This is useful as it means children can get the right medication as a result of observational learning and reduce unnecessary problems [3]

- (g)* Discuss ethical considerations in relation to the social area. Support your answer with examples from relevant core studies.

~~social~~ The social area as a whole can be considered fairly unethical as for accurate natural study of interaction between people it is often required they aren't aware they are taking place in a study. In Milgram and Levis studies participants weren't ^{unaware} they were participating. This meant ethical considerations like consent, deception and the right to withdraw were all broken and perhaps even protection from harm as in Milgram's study participants may have felt anxiety or distress at the cost of the model. Milgram's study however, undoubtably breaches the most ethical considerations of us even from the beginning of the study the participants are deceived as to the true nature and aims and also by the other participants which they aren't aware is a confederate. Although at first it may have seemed like they had consented the verbal cues for pain from the researcher made the participants feel as though this wasn't a real option. All participants were left shaking, lip biting or shivering and one participant even suffered a seizure mainly participants by no means were protected from harm. However, Milgram ensured the confidentiality

consideration was not broken as after participant debrief
they were asked to consent to their information being used.
Borrellino's study is more ethically considerate as participants
knew they were in a study although deceived to the ends.
This is often accepted as good science in some circumstances [12]

Turn over for the next question

SECTION C – Practical applications

Answer all the questions.

Brazilian athlete gives up chance of winning to help struggling Mexican cross the finishing line

A dazed and struggling Mexican athlete was helped over the finishing line by a top-class Brazilian runner at the end of a marathon race in Brazil yesterday.

The Mexican runner was just in the lead as competitors headed into the final kilometre but then the heat began to take its toll and he started to weave across the course. The Brazilian runner, who was not far behind in second place, caught up, put his arm around the struggling Mexican and all but carried him along the final few hundred metres so he could cross the finishing line. An American runner did not stop to help but overtook them to win the race.

When asked later why he had given up his chance of winning the race, the Brazilian said, "It was an easy thing to do. In Brazil we are always encouraged to be friendly, helpful and agreeable. Such behaviours are valued over achievement."

The American runner, who won the race, when asked why he didn't stop to help said it was the Mexican's own fault he was affected so badly by the heat. He should have done more training in hot climates like this one in Brazil. He also said that his coach had told him that he should always try to win all races, regardless of the physical or mental costs or his moral beliefs, so he was only obeying orders.

Based on an article from The Guardian's sport section found on-line.

- 9 (a) Identify **two** psychological issues raised by the article above. Support your answer with evidence from the article.

One issue raised is the extent to which helping behavior is different across cultures. As shown in Lein's research Rio de Janeiro uses the most helpful city in the article it states 'In Brazil we are always encouraged to be friendly etc opposed to America who has been taught more individualist values except concerning helping behavior. Another issue is obedience or learnt/initiated behavior the American states he was 'only obeying others' orders which he would have been taught in a different way to the Brazilian. In Lein's finding the American City of New York uses a maner of the lowest for helping behavior showing cultural differences in obedience and aspects like sympathy are psychological issues raised.

[6]

DO NOT WRITE IN THIS MARGIN

- (b) Briefly consider the individual/situational debate in relation to the article above. Support your answer with evidence from the article.

In relation to the GAO article it supports the situational side of the debate for example such behaviours are valued over achievement. It shows the importance of certain factors in different cultures which is taught as part of their upbringing from those around them. This differs to other cultures where separate values are taught such as 'always try to win at races regardless of physical or mental costs or moral beliefs' although this demonstrates the role of situational factors and feelings of success which vary in different situations for example the Americans moral beliefs may have meant he had acted differently in a different environment. [5]

- (c) Outline Piliavkin et al.'s 'Subway Samaritan' study and describe ways in which it could relate to the article. Support your answer with evidence from the article.

Piliavkin's 'Subway Samaritan' consisted of 16 researchers two acting as recorders and one male as the 'ill' or 'drunk' person and one as the model who would intervene after 70 or 180 seconds. ~~The ill or drunk person has fear~~ variables were tested which were the responsibility for the person being in that situation operationalised as ill or drunk, their race - black or white - the size of the group on the train and the intervention of the model. Piliavkin found people were likely to help the 'ill' person more than the drunk and if that help happened fast it was more likely others will. This relates to the article as it shows ~~nowas~~ someone who is ill or 'heat begun to take its toll' can more likely to receive help. However as the American saw the Mexican's 'illness' as his 'own fault' this may have been why he didn't help as like the 'drunk' condition less help helpers demonstrated when it appeared as though it was the person's own responsibility. [8]

- (d) Using your psychological knowledge, suggest two ways in which positive helping behaviours may be encouraged in athletes from countries such as America.

One way it could be encouraged is through observational learning & operant conditioning. This consists of aspects of positive reinforcement. It may include an American athlete witnessing a Brazilian e.g. someone from Brazil helping someone in a situation e.g. hurt leg in a race. The participant from Brazil may get more praise than someone who had won the race simply for their helpful actions. An American athlete may observe and imitate this themselves, when they are rewarded for their good behavior, like in children, they may well be more likely to repeat the positive behaviour again opposed to no attorney and not receiving praise. Another way it could be encouraged is by coach/athlete, coaches, peers and parents. Sympathy is a cultural aspect but also one that is taught. If an American athlete may not have been brought up in such environment they can be taught in in their sport. If it is witnessed and exaggerated by those around them it is more likely to be imitated by them.

- (e)* Evaluate the suggestions you made in 9(d) using issues and debates you have learned about in psychology.

~~It may raise ethical~~ In relation to the situational/ individual debate it goes against the cultural values taught in American athletes from their peers and society. Having learned to do to behave and having learned the morals of their own culture it may be difficult for them see positive aspects and take on the values of other cultures which may differ from their own. In relation to the free will/deterministic debate it may be seen to restrict free will. Although behavior is only encouraged it does many restricts the American athletes free will as surely it is up to the individual how and what behaviours they should adopt. To ethical considerations like consent may also be an issue here as if those behaviors or types of learning behaviors are displayed in training athletes they may not get a fair choice as to whether they will adopt them. [8]

END OF QUESTION PAPER

ADDITIONAL ANSWER SPACE

If additional space is required, you should use the following lined page(s). The question number(s) must be clearly shown in the margin(s).

1x

Certain types of learning e.g operant conditioning and are often influenced by individual factors. These factors are all influenced or 'products' of our environment however, different. There may be individual differences but an alternative is more of a reductionist approach stating that differences individual differ in personality, emotion, cognition and behaviour and not including alternate factors like the individual influence of our environment or by biology. However, to some extent the behaviour perspective too ignores individual differences so the two areas and perspectives can be seen in contrast.

2x

In this study for example, the participants needed and rightly were deceived without harm for research. In this study a pilot test beforehand was also done to test not only the procedure but if the pilot participants once aware felt they had the need for their deception wasn't unethical showing how this study had higher consideration for participants in terms of ethics.
